---

The following Pfam domain model PF00311.9 of the Phosphoenolpyruvate carboxylase is 960 positions long. Its breakpoint score occurs at 11.7 with corresponding E-value of 3.03. Beyond the breakpoint, the E-value underwent an exaggeration where its magnitude increases with large score. In the most extreme case, the largest significant hit Q01647.1 with score of 2796.7 has its EVD E-value of 8e-11 scaled all the way to the logistic E-value of 0. The order of magnitude difference is extremely big.

On the other hand, we also have hits with EVD E-value > 0.1 that shows stretches of impressive sequence matches but deemed as insignificant under the EVD statistical model. Given the length of this particular model, the global-mode can drastically under-sample random sequence matches and thus creates extremely small lambda. This leads to the underestimation of significance for those good hits with large EVD E-value.

For these long domain models, the EVD statistical model can generally underestimate the significance of sequence matches. Yet ironically, it exaggerates the significance for hits with larger scores. In hindsight, the lack of sequence sampling in between the extremes of E-values is just an illusion that is created by the switching between 2 statistical models (EVD and logistic).
